The Euler's Function

Yoshinori Fujisawa

Summary. This article is concerned with the Euler's function [10] that plays an important role in cryptograms. In the first section, we present some selected theorems on integers. Next, we define the Euler's function. Finally, three theorems relating to the Euler's function are proved. The third theorem concerns two relatively prime integers which make up the Euler's function parameter. In the public key cryptography these two integer values are used as public and secret keys.

The articles [11], [7], [14], [4], [3], [12], [1], [13], [2], [9], [8], [15], [5], and [6] provide the notation and terminology for this paper.

1. Preliminary

We adopt the following convention: a, b, c, k, l, m, n denote natural numbers and i, j, x, y denote integers.

The following propositions are true:

(1) For all natural numbers k, n holds $k \in n$ iff $k < n$.

(2) n and n are relative prime iff $n = 1$.

(3) If $k \neq 0$ and $k < n$ and n is prime, then k and n are relative prime.

(4) n is prime and $k \in \{k_1; k_1$ ranges over natural numbers: n and k_1 are relative prime $\wedge\ k_1 \geq 1 \wedge\ k_1 \leq n\}$ if and only if n is prime and $k \in n$ and $k \notin \{0\}$.

(5) For every finite set A and for every set x such that $x \in A$ holds $\overline{\overline{A \setminus \{x\}}} = \overline{\overline{A}} - \overline{\overline{\{x\}}}$.

(6) If $\gcd(a,b) = 1$, then for every c holds $\gcd(a \cdot c, b \cdot c) = c$.

(7) If $a \neq 0$ and $b \neq 0$ and $c \neq 0$ and $\gcd(a \cdot c, b \cdot c) = c$, then a and b are relative prime.

(8) If $\gcd(a,b) = 1$, then $\gcd(a+b,b) = 1$.

(9) For every c holds $\gcd(a + b \cdot c, b) = \gcd(a,b)$.

(10) Suppose m and n are relative prime. Then there exists k such that

(i) there exist integers i_0, j_0 such that $k = i_0 \cdot m + j_0 \cdot n$ and $k > 0$, and

(ii) for every l such that there exist integers i, j such that $l = i \cdot m + j \cdot n$ and $l > 0$ holds $k \leq l$.

(11) If m and n are relative prime, then for every k there exist i, j such that $i \cdot m + j \cdot n = k$.

(12) For all non empty finite sets A, B such that there exists a function from A into B which is one-to-one and onto holds $\overline{\overline{A}} = \overline{\overline{B}}$.

(13) For all integers i, k, n holds $(i + k \cdot n) \bmod n = i \bmod n$.

(14) If $a \neq 0$ and $b \neq 0$ and $c \neq 0$ and $c \mid a \cdot b$ and a and c are relative prime, then $c \mid b$.

(15) Suppose $a \neq 0$ and $b \neq 0$ and $c \neq 0$ and a and c are relative prime and b and c are relative prime. Then $a \cdot b$ and c are relative prime.

(16) If $x \neq 0$ and $y \neq 0$ and $i > 0$, then $i \cdot x \gcd i \cdot y = i \cdot (x \gcd y)$.

(17) For every x such that $a \neq 0$ and $b \neq 0$ holds $a + x \cdot b \gcd b = a \gcd b$.

2. Euler's Function — Definition and theorems

Let n be a natural number. The functor Euler n yielding a natural number is defined as follows:

(Def. 1) $\text{Euler}\, n = \overline{\overline{\{k; k \text{ ranges over natural numbers: } n \text{ and } k \text{ are relative prime } \wedge\ k \geq 1 \wedge\ k \leq n\}}}$.

One can prove the following proposition

(18) $\text{Euler}\, 1 = 1$.

Next we state four propositions:

(19) $\text{Euler}\, 2 = 1$.

(20) If $n > 1$, then $\text{Euler}\, n \leq n - 1$.

(21) If n is prime, then $\text{Euler}\, n = n - 1$.

(22) If $m > 1$ and $n > 1$ and m and n are relative prime, then $\text{Euler}\, m \cdot n = \text{Euler}\, m \cdot \text{Euler}\, n$.

Acknowledgments

The authors wish to thank Professor A. Trybulec for all his advice on this article.
