1. INTRODUCTION

In this paper A denotes a set and k, m, n denote natural numbers.

The scheme *Regr1* deals with a natural number \mathcal{A} and a unary predicate \mathcal{P} , and states that:

For every k such that $k \leq \mathcal{A}$ holds $\mathcal{P}[k]$

provided the parameters meet the following conditions:

- $\mathcal{P}[\mathcal{A}]$, and
- For every k such that $k < \mathcal{A}$ and $\mathcal{P}[k+1]$ holds $\mathcal{P}[k]$.

Let n be a natural number. Note that $\text{Seg}(n+1)$ is non empty.

Let X be a non empty set and let R be an order in X . Note that $\langle X, R \rangle$ is non empty.

The following proposition is true

$$(1) \quad \emptyset|^2 A = \emptyset.$$

Let X be a set. Observe that there exists a subset of $\text{Fin}X$ which is non empty.

Let X be a non empty set. One can check that there exists a subset of $\text{Fin}X$ which is non empty and has non empty elements.

Let X be a non empty set and let F be a non empty subset of $\text{Fin}X$ with non empty elements.

Note that there exists an element of F which is non empty.

Let I_1 be a set. We say that I_1 has a non-empty element if and only if:

(Def. 1) There exists a non empty set X such that $X \in I_1$.

One can verify that there exists a set which has a non-empty element.

Let X be a set with a non-empty element. Note that there exists an element of X which is non empty.

Let us observe that every set which has a non-empty element is also non empty.

Let X be a non empty set. Note that there exists a subset of $\text{Fin}X$ which has a non-empty element.

Let X be a non empty set, let R be an order in X , and let A be a subset of X . Then $R|^2 A$ is an order in A .

The scheme *SubFinite* deals with a set \mathcal{A} , a subset \mathcal{B} of \mathcal{A} , and a unary predicate \mathcal{P} , and states that:

$$\mathcal{P}[\mathcal{B}]$$

provided the following conditions are met:

- \mathcal{B} is finite,
- $\mathcal{P}[\mathcal{0}_{\mathcal{A}}]$, and
- For every element x of \mathcal{A} and for every subset B of \mathcal{A} such that $x \in B$ and $B \subseteq \mathcal{B}$ and $\mathcal{P}[B]$ holds $\mathcal{P}[B \cup \{x\}]$.

One can prove the following proposition

- (2) Let F be a non empty poset and A be a subset of F . Suppose A is finite and $A \neq \emptyset$ and for all elements B, C of F such that $B \in A$ and $C \in A$ holds $B \leq C$ or $C \leq B$. Then there exists an element m of F such that $m \in A$ and for every element C of F such that $C \in A$ holds $m \leq C$.

Let X be a non empty set and let F be a subset of $\text{Fin}X$ with a non-empty element. Note that there exists an element of F which is finite and non empty.

Let P be a non empty poset, let A be a non empty finite subset of P , and let x be an element of P . One can check that $\text{InitSegm}(A, x)$ is finite.

The following proposition is true

- (3) For all finite sets A, B such that $A \subseteq B$ and $\text{card}A = \text{card}B$ holds $A = B$.

Let X be a set, let A be a finite subset of X , and let R be an order in X . Let us assume that R linearly orders A . The functor $\text{SgmX}(R, A)$ yielding a finite sequence of elements of X is defined by the conditions (Def. 2).

(Def. 2)(i) $\text{rng SgmX}(R, A) = A$, and

- (ii) for all natural numbers n, m such that $n \in \text{dom SgmX}(R, A)$ and $m \in \text{dom SgmX}(R, A)$ and $n < m$ holds $(\text{SgmX}(R, A))_n \neq (\text{SgmX}(R, A))_m$ and $\langle (\text{SgmX}(R, A))_n, (\text{SgmX}(R, A))_m \rangle \in R$.

We now state the proposition

- (4) Let X be a set, A be a finite subset of X , R be an order in X , and f be a finite sequence of elements of X . Suppose $\text{rng } f = A$ and for all natural numbers n, m such that $n \in \text{dom } f$ and $m \in \text{dom } f$ and $n < m$ holds $f_n \neq f_m$ and $\langle f_n, f_m \rangle \in R$. Then $f = \text{SgmX}(R, A)$.

2. ABSTRACT COMPLEXES

Let C be a non empty poset. The functor $\text{simplexes}(C)$ yields a subset of Fin (the carrier of C) and is defined as follows:

(Def. 3) $\text{simplexes}(C) = \{A; A \text{ ranges over elements of } \text{Fin} \text{ (the carrier of } C\text{): the internal relation of } C \text{ linearly orders } A\}$.

Let C be a non empty poset. Note that $\text{simplexes}(C)$ has a non-empty element.

In the sequel C is a non empty poset.

One can prove the following propositions:

- (5) For every element x of C holds $\{x\} \in \text{simplexes}(C)$.
- (6) $\emptyset \in \text{simplexes}(C)$.
- (7) For all sets x, s such that $x \subseteq s$ and $s \in \text{simplexes}(C)$ holds $x \in \text{simplexes}(C)$.

Let X be a set and let F be a non empty subset of $\text{Fin}X$. Observe that every element of F is finite.

Let X be a set and let F be a non empty subset of $\text{Fin}X$. We see that the element of F is a subset of X .

Next we state three propositions:

- (8) Let X be a set, A be a finite subset of X , and R be an order in X . If R linearly orders A , then $\text{SgmX}(R, A)$ is one-to-one.

(9) Let X be a set, A be a finite subset of X , and R be an order in X . If R linearly orders A , then $\text{lenSgmX}(R, A) = \overline{A}$.

(10) Let C be a non empty poset and A be a non empty element of $\text{simplexes}(C)$. If $\overline{A} = n$, then $\text{domSgmX}(\text{the internal relation of } C, A) = \text{Seg } n$.

Let C be a non empty poset. One can check that there exists an element of $\text{simplexes}(C)$ which is non empty.

3. TRIANGULATIONS

A set sequence is a many sorted set indexed by \mathbb{N} .

Let I_1 be a set sequence. We say that I_1 is lower non-empty if and only if:

(Def. 4) For every n such that $I_1(n)$ is non empty and for every m such that $m < n$ holds $I_1(m)$ is non empty.

Let us note that there exists a set sequence which is lower non-empty.

Let X be a set sequence. The functor $\text{FuncsSeq}(X)$ yielding a set sequence is defined as follows:

(Def. 5) For every natural number n holds $(\text{FuncsSeq}(X))(n) = X(n)^{X(n+1)}$.

Let X be a lower non-empty set sequence and let n be a natural number. One can check that $(\text{FuncsSeq}(X))(n)$ is non empty.

Let us consider n and let f be an element of $(\text{Seg}(n+1))^{\text{Seg } n}$. The functor $@f$ yields a finite sequence of elements of \mathbb{R} and is defined as follows:

(Def. 6) $@f = f$.

The set sequence NatEmbSeq is defined by:

(Def. 7) For every natural number n holds $(\text{NatEmbSeq})(n) = \{f; f \text{ ranges over elements of } (\text{Seg}(n+1))^{\text{Seg } n}: @f \text{ is increasing}\}$.

Let us consider n . One can verify that $(\text{NatEmbSeq})(n)$ is non empty.

Let n be a natural number. Observe that every element of $(\text{NatEmbSeq})(n)$ is function-like and relation-like.

Let X be a set sequence. A triangulation of X is a many sorted function from NatEmbSeq into $\text{FuncsSeq}(X)$.

We introduce triangulation structures which are systems

$\langle \text{a skeleton sequence, a faces assignment} \rangle$,

where the skeleton sequence is a set sequence and the faces assignment is a many sorted function from NatEmbSeq into FuncsSeq (the skeleton sequence).

Let T be a triangulation structure. We say that T is lower non-empty if and only if:

(Def. 9)¹ The skeleton sequence of T is lower non-empty.

One can check that there exists a triangulation structure which is lower non-empty and strict.

Let T be a lower non-empty triangulation structure. Note that the skeleton sequence of T is lower non-empty.

Let S be a lower non-empty set sequence and let F be a many sorted function from NatEmbSeq into $\text{FuncsSeq}(S)$. Observe that $\langle S, F \rangle$ is lower non-empty.

¹ The definition (Def. 8) has been removed.

4. RELATIONSHIP BETWEEN ABSTRACT COMPLEXES AND TRIANGULATIONS

Let T be a triangulation structure and let n be a natural number. A simplex of T and n is an element of (the skeleton sequence of T)(n).

Let n be a natural number. A face of n is an element of $(\text{NatEmbSeq})(n)$.

Let T be a lower non-empty triangulation structure, let n be a natural number, let x be a simplex of T and $n + 1$, and let f be a face of n . Let us assume that (the skeleton sequence of T)($n + 1$) $\neq \emptyset$. The functor $\text{face}(x, f)$ yielding a simplex of T and n is defined by:

(Def. 10) For all functions F, G such that $F = (\text{the faces assignment of } T)(n)$ and $G = F(f)$ holds $\text{face}(x, f) = G(x)$.

Let C be a non empty poset. The functor $\text{Triang}(C)$ yields a lower non-empty strict triangulation structure and is defined by the conditions (Def. 11).

- (Def. 11)(i) (The skeleton sequence of $\text{Triang}(C)$)(0) = $\{\emptyset\}$,
- (ii) for every natural number n such that $n > 0$ holds (the skeleton sequence of $\text{Triang}(C)$)(n) = $\{\overline{\text{SgmX}}(\text{the internal relation of } C, A); A \text{ ranges over non empty elements of } \text{simplexes}(C): \overline{A} = n\}$, and
- (iii) for every natural number n and for every face f of n and for every element s of (the skeleton sequence of $\text{Triang}(C)$)($n + 1$) such that $s \in (\text{the skeleton sequence of } \text{Triang}(C))(n + 1)$ and for every non empty element A of $\text{simplexes}(C)$ such that $\text{SgmX}(\text{the internal relation of } C, A) = s$ holds $\text{face}(s, f) = \text{SgmX}(\text{the internal relation of } C, A) \cdot f$.
